Exercise 11.1.1

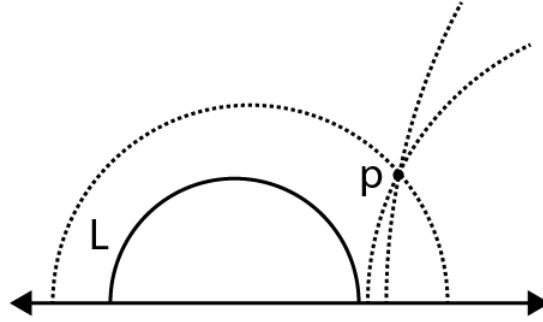

Show that, if l is a half-line geodesic in \mathbb{H} and a is a point not on l , there are infinitely many hyperbolic lines passing through a that do not intersect l .

Preliminary Statements

Euclid's parallel postulate states that, in euclidean geometry, if there is a point p not on a line l , there is exactly one line parallel to l going through p .

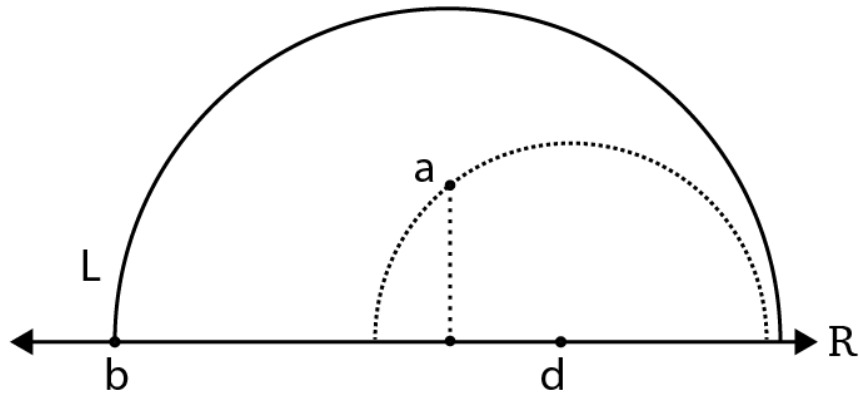

This is not true in hyperbolic geometry; rather, there are infinitely many lines parallel to l passing through p .

Solution

Let l meet the real axis at point b , and let the real component of $a > b$.

The semicircle with a center d on the real axis and radius $|a - d|$ passes through a and does not meet l if $|a - d| \leq |d - b|$.
